

/// Fine Colored Glass Powders

The colored glass is produced by melting lead crystal glass with heavy metal oxides, thus a wide variety of colors is achieved. The light fastness of all colored glass powders is excellent (8,8,8). The colored glass pigments can be used in all media, such as oil, acrylic dispersions, lime and all kinds of glues. In certain mortars and cements the pigments may cause blooming. For application in exterior environments it is advisable to do trials first.

The colored glass is crushed and then ground to a gritty powder of about 0,25 mm. The powder is then sieved.

We offer the glass powder in 5 different grades:

Safety advice: Avoid formation of dust. Do not inhale dust.

- 1 **Grade < 63 µ:** The finest powder is also the lightest powder, it easily can be worked with the brush in any media (e.g. watercolor, print, glazing, etc.).
- 2 **Grade 63 – 80 µ:** The fine powder can easily be used in all media, its coloring strength is better than grade 1.
- 3 **Grade 80 – 100 µ:** The coarse powder gives brilliance and body to the paint, but it is too coarse to be applied in watercolor or glazing techniques. The glass particles can be seen in thin layers.
- 4 **Grade 100 – 125 µ:** The powder has a sandy texture and can be strewn, the glass particles show a glittering surface.
- 5 **Grade > 125 µ:** the particles can be literally moved around on the surface, ideal for fresco techniques and sand-like textures.
